FLEXIBLE WEB PAGE TEMPLATE BUILDING SYSTEM AND METHOD

This application is a divisional of prior application Ser. No. 12/060,254, filed Mar. 31, 2008, which is hereby incorporated by reference in its entirety.

FIELD OF THE INVENTION

This invention relates to creation and design of electronic documents and, more particularly, to flexible web page template building techniques and systems.

BACKGROUND OF THE INVENTION

Customizable web page templates for designing websites assist people in quickly designing web pages for publishing to a web hosting server.

One of the challenges in designing web page templates whose content may be customized by end users is that the size of the content or amount of text that may be inserted into the editable areas of the web page may vary from user to user. Because a web page generally provides a header area, a navigational area, and a bottom border around editable areas that may be customized by a user, the template design required some knowledge of the size of the editable areas. Previously, this has caused template providers to set a static size editable area, thereby limiting the amount of content that the user can insert in the editable areas.

Another challenge for the designers of web page templates is the desirability of making web page themes work in all types of browsers.

Accordingly, it would be desirable to provide a web page generating tool that has a simple user interface and allows a web page designer to create flexible auto-expanding editable areas which grow and shrink based on the amount of content inserted into the editable areas, and to design themes that work in a wide variety of browsers.

SUMMARY OF THE INVENTION

Embodiments of the invention are directed to flexible web page template building techniques and systems which allow web page designers to build auto-expanding web pages that grow and shrink according to an amount of user content inserted there.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a diagrammatic representation of a web page template building plugin.

FIG. 2 is a block diagram illustrating a network environment in which an embodiment of the invention operates.

FIG. 3 is a block diagram illustrating a user computer environment in which an electronic publishing tool may operate.

FIG. 4 is a screen shot view of an example user interface display 400 of an example web page template building tool.

FIG. 5A is an example auto-expanding user-editable content container illustrating application of the guides, in particular with respect to a variation in the vertical direction of content between the guides.

FIG. 5B illustrates the auto-expanding user-editable content container of FIG. 5A where the guides are set to a position which comprises variation in the vertical direction of content between the guides.

2

FIG. 6A is an example auto-expanding use-editable content container illustrating application of the guides, in particular with respect to a repeating pattern.

FIG. 6B illustrates the auto-expanding user-editable content container of FIG. 6A where the guides are set to a position resulting in a non-repeating pattern.

FIG. 7A illustrates the partitioning of a vertical navigational area to grow and shrink as navigation buttons are added and removed.

FIG. 7B illustrates the partitioning of a horizontal navigational area to grow and shrink as navigation buttons are added and removed.

FIG. 8 is an exemplary table created to describe an outer and inner background of a web page template.

FIG. 9 is an exemplary web page template layout.

FIG. 10 is a diagram illustrating sections of the web page template that are rasterized into separate images.

FIG. 11 is an HTML table illustrating an example web page template.

FIG. 12 is a flowchart of an exemplary embodiment of the operation of an auto-expanding user-editable content container when content is added by an end user.

FIG. 13 is a flowchart of an exemplary embodiment of the operation of an auto-expanding navigational area when navigation buttons are added or removed from a navigational area by an end user.

DETAILED DESCRIPTION

Embodiments of the invention implement a flexible website template building tool. In an embodiment, an electronic document design tool used to design customized electronic designs which may be published electronically or printed to generate a printed product includes a website template builder add-in which allows a designer to customize a website template based on elements of an electronic design. For example, FIG. 1 shows diagrammatically, an electronic design tool for printed products 2 which receives or creates an electronic version of a printed product design 1. The electronic design tool 2 includes a website add-in control 3 which, when activated, generates a web page template 4 including at least one element from the printed product design 1.

Web page templates 4 may be valuable to website hosting service providers that provide tools to customers to build their websites. Web page templates 4 may also be valuable to designers of electronic, printed, and other types of products who wish to cross-sell a website to a customer of an electronic, printed, or other type of product while retaining some of the design features of the other product.

For example, FIG. 2 illustrates a networked system 10. Client System 11 represents a user's computer system, for example, a customer of a website hosting service. Client system 11 is a typically equipped modern personal computer, discussed with reference to FIG. 3, being configured to communicate over the Web and running a modern Web browser program 12. For purposes of discussion, the invention will be described in the context of a personal computer running the Microsoft Internet Explorer browser, but it will be appreciated that the invention can be applied to other browser programs that support HTML, XHTML, DHTML, XML, and other web functionality and to other intelligent devices, such as PDAs capable of running such a browser.

Client 11 communicates with a website hosting service server 20 to set up account information and order website hosting services via the client's browser 12. After setting up an account, the website hosting customer may then begin designing and editing their website. In an exemplary embodi-

3

ment, the website hosting service provides website building tools via website building tools server 30. In an embodiment, the client 11 may download a website building tool 31 to execute in their local browser 12.

The website building tool 31 allows the website hosting services customer to download web page templates (stored in a web page template gallery 40) from the website building tools server 30. Website templates are electronic web page designs that include editable areas to allow the customer to customize text, image, and design content. They typically include a background with or without a design, a header area, a navigational menu area, and one or more user-editable content areas. The website hosting services customer may edit and design a number of customized web pages to form a customized website which may be published to a hosted website database 50. When a web page is published to the hosted websites database 50, a website hosting server 60 will serve web pages of the hosted customized website to other networked clients on the network, such as client 70.

Web page templates may be created by a content designer operating a content provider computer system 80, which may be any conventional computer system, for example, as described in reference to FIG. 3. An electronic document creation and editing application 82 executes on the content provider system 80, either locally, or remotely via a conventional networked configuration (not shown), and allows the content provider to create electronic documents, for example documents that may be printed or viewed on a display. The electronic document creation and editing application 82 may also open and edit previously designed documents. For example, the website hosting sales server 20 may also be an online printed and electronic products retailer which offers products such as business cards, postcards, brochures, etc. to customers, for example client 70. The server 20 may thus provide customizable designs or templates (stored in product template database 42) that may be edited by a customer of the online printed and electronic products retailers and then ordered for printing/publishing and delivery to the customer. Customized product designs may be subsequently stored (in a customers customized products database 44) for future access by the retailer to allow the customer to return to the website and reorder the customized products.

The electronic document creation and editing application 82 may itself provide, or may merely provide access to, a web page template building tool 84. For example, a conventional electronic document publishing system may include an add-in or plug-in. A plugin is a computer program that interacts with a host application (for example, the electronic document creation and editing application 82) to provide a function "on demand". Alternatively, the electronic document creation and editing application 82 may itself implement the functionality for automatically creating web page templates.

The web page template building tool 84 automatically generates web page templates based on electronic documents, the details of which are presented hereinafter.

Turning now to FIG. 3, there is presented an example of a suitable computing system environment 100 which may implement any and all the clients 11, 70, servers 20, 30, 60, and content provider system 80. The computing system environment 100 is only one example of a suitable computing environment and is not intended to suggest any limitation as to the scope of use or functionality of the invention. Neither should the computing environment 100 be interpreted as having any dependency or requirement relating to any one or combination of components illustrated in the exemplary operating environment 100.

4

Embodiments of the invention are operational with numerous other general purpose or special purpose computing system environments or configurations. Examples of well known computing systems, environments, and/or configurations that may be suitable for use with the invention include, but are not limited to, personal computers, server computers, hand-held or laptop devices, multiprocessor systems, microprocessor-based systems, set top boxes, programmable consumer electronics, network PCs, minicomputers, mainframe computers, distributed computing environments that include any of the above systems or devices, and the like.

Embodiments of the invention, and in particular, the website building tool 31 and its target-alignment-and-drop control 32 integrated therein, may be described in the general context of computer-executable instructions, such as program modules, being executed by a computer. Generally, program modules include routines, programs, objects, components, data structures, etc. that perform particular tasks or implement particular abstract data types. Embodiments of the invention may also be practiced in distributed computing environments where tasks are performed by remote processing devices that are linked through a communications network or other data transmission medium. In a distributed computing environment, program modules and other data may be located in both local and remote computer storage media including memory storage devices.

With reference to FIG. 3, an exemplary system for implementing the invention includes a general purpose computing device in the form of a computer 110. Components of computer 110 may include, but are not limited to, a processing unit 120, a system memory 130, and a system bus 121 that couples various system components including the system memory to the processing unit 120. The system bus 121 may be any of several types of bus structures including a memory bus or memory controller, a peripheral bus, and a local bus using any of a variety of bus architectures.

Computer 110 typically includes a variety of computer readable media. Computer readable media can be any available media that can be accessed by computer 110 and includes both volatile and nonvolatile media, removable and non-removable media. By way of example, and not limitation, computer readable media may comprise computer storage media and communication media. Computer storage media includes volatile and nonvolatile, removable and non-removable media implemented in any method or technology for storage of information such as computer readable instructions, data structures, program modules or other data. Computer storage media includes, but is not limited to, RAM, ROM, EEPROM, flash memory or other memory technology, CDROM, digital versatile disks (DVD) or other optical disk storage, magnetic cassettes, magnetic tape, magnetic disk storage or other magnetic storage devices, or any other medium which can be used to store the desired information and which can be accessed by computer 110. Communication media typically embodies computer readable instructions, data structures, program modules or other data in a modulated data signal such as a carrier wave or other transport button and includes any information delivery media.

The system memory 130 includes computer storage media in the form of volatile and/or nonvolatile memory such as read only memory (ROM) 131 and random access memory (RAM) 132. A basic input/output system 133 (BIOS), containing the basic routines that help to transfer information between elements within computer 110, such as during start-up, is typically stored in ROM 131. RAM 132 typically contains data and/or program modules that are immediately accessible to and/or presently being operated on by process-

5

ing unit **120**. By way of example, and not limitation, FIG. **3** illustrates operating system **134**, application programs **135**, other program modules **136**, and program data **137**.

The computer **110** may also include other removable/non-removable, volatile/nonvolatile computer storage media. By way of example only, FIG. **3** illustrates a hard disk drive **140** that reads from or writes to non-removable, nonvolatile magnetic media, a magnetic disk drive **151** that reads from or writes to a removable, nonvolatile magnetic disk **152**, and an optical disk drive **155** that reads from or writes to a removable, nonvolatile optical disk **156**, such as a CD ROM or other optical media. Other removable/non-removable, volatile/nonvolatile computer storage media that can be used in the exemplary operating environment include, but are not limited to, magnetic tape cassettes, flash memory cards, digital versatile disks, digital video tape, solid state RAM, solid state ROM, and the like. The hard disk drive **141** is typically connected to the system bus **121** through a non-removable memory interface such as interface **140**, and magnetic disk drive **151** and optical disk drive **155** are typically connected to the system bus **121** by a removable memory interface, such as interface **150**.

The drives and their associated computer storage media discussed above and illustrated in FIG. **3**, provide storage of computer readable instructions, data structures, program modules and other data for the computer **110**. In FIG. **3**, for example, hard disk drive **141** is illustrated as storing operating system **144**, application programs **145**, other program modules **146**, and program data **147**. Note that these components can either be the same as or different from operating system **134**, application programs **135**, other program modules **136**, and program data **137**. Operating system **144**, application programs **145**, other program modules **146**, and program data **147** are given different numbers here to illustrate that, at a minimum, they are different copies. A user may enter commands and information into the computer **20** through input devices such as a keyboard **162** and pointing device **161**, commonly referred to as a mouse, trackball or touch pad. Other input devices (not shown) may include a microphone, joystick, game pad, satellite dish, scanner, or the like. These and other input devices are often connected to the processing unit **120** through a user input interface **160** that is coupled to the system bus, but may be connected by other interface and bus structures, such as a parallel port, game port or a universal serial bus (USB). A monitor **191** or other type of display device is also connected to the system bus **121** via an interface, such as a video interface **190**. In addition to the monitor, computers may also include other peripheral output devices such as speakers **197** and printer **196**, which may be connected through an output peripheral interface **190**.

The computer **110** may operate in a networked environment using logical connections to one or more remote computers, such as a remote computer **180**. The remote computer **180** may be a personal computer, a server, a router, a network PC, a peer device or other common network node, and typically includes many or all of the elements described above relative to the computer **110**, although only a memory storage device **181** has been illustrated in FIG. **3**. The logical connections depicted in FIG. **3** include a local area network (LAN) **171** and a wide area network (WAN) **173**, but may also include other networks. Such networking environments are commonplace in offices, enterprise-wide computer networks, intranets and the Internet.

When used in a LAN networking environment, the computer **110** is connected to the LAN **171** through a network interface or adapter **170**. When used in a WAN networking environment, the computer **110** typically includes a modem

6

172 or other means for establishing communications over the WAN **173**, such as the Internet. The modem **172**, which may be internal or external, may be connected to the system bus **121** via the user input interface **160**, or other appropriate button. In a networked environment, program modules depicted relative to the computer **110**, or portions thereof, may be stored in the remote memory storage device. By way of example, and not limitation, FIG. **3** illustrates remote application programs **185** as residing on memory device **181**. It will be appreciated that the network connections shown are exemplary and other means of establishing a communications link between the computers may be used.

Referring back to FIG. **2**, each web page template in the web page template gallery **40** represents a thematic design of a single page of a website. As previously explained, in order for the website building tool **122** to offer web page templates, such templates must first be created. In one embodiment, electronic document creation and editing application **82**, such as Adobe® InDesign, which are intended for design of products to be printed, are utilized to take advantage of content developed for printed products. In an embodiment, the electronic document and editing application **82** is configured with a website plugin which, in accordance with the invention described herein, assists the customer in generating a website template based on a printed or electronic product design.

FIG. **4** is a screen shot view of an example user interface display **400** of an example web page template building tool. For example, the web page template building tool may exist as a standalone application, may be integrated into an electronic document creation and editing application, or may be a plugin to such an application. As illustrated in FIG. **4**, the user interface display **400** includes editing controls **401** known and standardly used within electronic document creation and editing applications, and a workspace **402** for designing a web page template **410**.

The web page template **410** assumes an 800-wide-pixel displayable page area, but of course it is to be understood that this number may be varied depending on the intended browser and display types, and on future advances in the display technology. The web page template **410** includes an outer background **411** which represents what should appear on a display outside of the 800-wide-pixel displayable page area, and inner background **412** which covers the outer background within the 800-pixel-wide area, a header area **415**, a navigational area **420**, and at least one auto-expanding user-editable content container **430**. In the exemplary embodiment, the header area **415** includes two "headline" areas of text: one for "Company Name" **416** and one for "Company Message" **417**. Preferably, while the auto-expanding user-editable content container allows only web-safe fonts, the header area **415** can support non-web-safe fonts, for example fonts that are used in the customer's logo or business cards.

In order to maximize the size of text entered in the headline areas **416**, **417**, the current size of the text entered in the text area is determined using a Rich Text Editor, and the web page template building tool **82** automatically determines an amount to scale the current sized text to make the text the full width of the available text area, and then determines an amount to scale the current sized text to make the text the full height of the available text area. The web page template building tool **82** then selects the smaller of the horizontal scale and vertical scale, scales the user-input text by the smaller selected scale, and replaces the user-input text in the text area with the scaled text.

In order to support growing and shrinking of content in the auto-expanding user-editable content container(s) **430**, there are certain rules which must be applied in the design of the

web page template. For example, the outer background may only contain a solid color, vertical gradient, or repeated pattern so that as the auto-expanding user-editable content container(s) grow, any visible outer background area on a user's display will appear continuous. Furthermore, if a gradient is used and the page is long, the color at the bottom of the gradient is preferably used as a solid color below where the gradient is specified. The inner background preferably may only comprise a solid color.

The auto-expanding user-editable content container **430** is displayed with a pair of horizontal guides—an upper horizontal guide **431** and a lower horizontal guide **432**. The user content must intersect with both the upper guide and the lower guide. Preferably, a few lines of sample text are inserted in the auto-expanding user-editable content container to illustrate to the user the default styles and fonts. In an embodiment, the user content sample text may only comprises web-safe fonts (restricted list of about eight fonts) that are known to be supported by most web browsers.

In an embodiment, artwork can extend into the user content area, and is rendered behind the user content.

The upper guide **431** must be above the lower guide **432**. Any elements which cross the upper guide **431** or the lower guide **432** must cross both guides. Any elements which cross the guides **431**, **432** must be “growable”. To be growable, either: the element is a repeating pattern, or there is no variation in the vertical directions between the two guides **431**, **432** (that is, every row of pixels between the guides is the same as every other row.)

To illustrate the rules pertaining to the guides **431**, **432**, FIG. 5A depicts content inserted in an auto-expanding user-editable content container **500** that complies with the above rules. That is, there is no variation in the vertical direction in the parts of the frame **510** inserted in the auto-expanding user-editable content container **500** between the two guides **531**, **532**. FIG. 5B depicts content inserted in an auto-expanding user-editable content container **500** that violates the user content rules. In this embodiment, the center pointed portions **515a**, **515b** of the frame **511** have variation in the vertical direction between the two guides **531**, **532**. If desired, the “bad” design in FIG. **513** could be brought into compliance with the rules by simply moving the upper guide **531** below the pointed portions **515a**, **515b** of the frame **511**. However, by doing so, since the bottom half of the frame **511** may be expanded to fit more user content, the pointed portions **515a**, **515b** of the frame **511** will not remain vertically centered with respect to the top and bottom of the frame **511**.

In elements in the auto-expanding user-editable content container **400** that span both guides **431**, **432**, if there are multiple repeated patterns, the repeated frequency in the vertical direction must be the same, and the repeat should be as small as possible. This is because, in the final webpage, any patterns which cross the bottom guide must be matched up with the artwork below the bottom guide.

FIGS. 6A and 6B further illustrate the rules pertaining to the guides, in particular with respect to a repeating pattern. As shown in FIG. 6A, an auto-expanding user-editable content container **600** includes a repeating pattern of circles. If the guides **631**, **632** are placed as shown, the pattern between the guides may be grown, as shown. In FIG. 6B, the guides are placed so that the pattern between the guides **631**, **632** is not a repeating pattern. Thus, when the auto-expanding user-editable content container is grown by adding an instance of the pattern between the guides, the result is undesirable.

The content placed in an auto-expanding user-editable content container while using the web page template building tool is content that will appear as a background layer in the

final template. Thus, in the final template, any content in auto-expanding user-editable content container is flattened into a background layer. Thus, when an end user utilizes the template as a starting point in designing a web page, the end user will insert text and other content in the auto-expanding user-editable content container, which will appear over the flattened content inserted by the web page template designer.

Turning now to the navigation area **420** of FIG. 4, the navigation area **420** comprises two layers designated for navigation items—the first is a navigation button layer and the second is a navigation background layer. The navigation button layer includes six structural items: two for each “state” of button (regular, currently active page, and “hover”). For each state, there is an item that represents the button background and a text frame item that represents the button text.

When designing a website template, the designer will preferably keep the three buttons in order, equally spaced, and aligned on a point boundary. The buttons should be aligned horizontally or vertically, depending on the orientation of the navigation area. Artwork can be added to the button items, or be drawn on the navigation button layer in the same space. Any artwork in the navigation button layer outside of the boundaries of the button background objects are ignored.

The navigation background layer contains the structural item that represents the entire navigational area. This area must be above the upper guide, and to the left of the content area. The amount of spacing around it determines how much space is added to the navigational area in each direction, beyond the size of the buttons.

Preferably, the web page template supports two orientations for the navigational area: horizontal and vertical. In both cases, the buttons are always set to a fixed size, determined by the designer. In an embodiment, only a single row or a single column of buttons is supported.

Vertical navigational areas are always grown downward. Horizontal navigational areas grow as follows: If the navigational area is near the left edge of the page, the navigational area will grow to the right; if the navigational area is near the right edge of the page, the navigational area will grow to the left; otherwise, the navigational area will grow to the left and the right (from the center).

To support growing and shrinking of the navigation buttons, a navigational area **700** is automatically split into three “sections”, illustrated in FIG. 7A. The sections include the area **712a** from the top (or left **712b**, for horizontal navigational areas, shown in FIG. 7B) of the navigational area to the middle of the top button, the area **714a** from the middle of the top button to the middle of the second button (or middle of the left button to the middle of the second button, shown in FIG. 7B), and the area **716a** from the middle of the last button to the bottom (or right **716b**, for horizontal navigational areas, shown in FIG. 7B) of the navigational area.

When the navigational area is rendered, the second section **714a** (or **714b**) is repeated as many times as necessary to accommodate all buttons **705**.

In an exemplary embodiment, the web page template building tool configures the navigational area **420** with a control that allows an end user of the template to select between a horizontal or vertical navigation menu orientation, and select and edit names of the selected navigation buttons. Further, the control may be configured to automatically detect a condition in which the navigation area cannot be fully displayed in the horizontal orientation and generates a request to the customer to change the navigation menu orientation to a vertical orientation. Alternatively, the control may simply automatically change the navigation menu orientation to a vertical orientation when this condition occurs.

The navigational area control may be configured to automatically size the navigation buttons identically and automatically determines and sizes the navigation button names with identically sized font. In an exemplary implementation, the navigational area control performs the steps of: for each respective navigation button, automatically determining a size of text used for the navigation button name, determining an amount to scale the current sized text to make the text the full width of the navigation button, determining an amount to scale the current sized text to make the text the full height of the navigation button, selecting the smaller of the horizontal scale and vertical scale; selecting the smallest of each of the selected scales over all of the navigation buttons as the global navigation button scale; and scaling each of the navigation button names to the global navigation button scale.

Web page template building tool **84** creates HTML pages that handle a variable amount of customer text, growing the page as necessary and uses HTML that renders reliably in a wide variety of browsers.

In an embodiment, the web page template building tool **84** creates an outermost table, illustrated in FIG. **8**, to describe the outer and inner background. A “body” tag is used to describe the outer background, so that the outer background can also extend below the theme content. In either case, the rest of the content goes in the main content cell.

FIG. **9** shows the elements of the web page template. As illustrated, the template **900** includes an outer background **901**, an inner background, **902**, and an auto-expanding user-editable content container **930** with upper and lower guides **931**, **932**. The section between the two horizontal guides **931**, **932** is the “growable section”.

To create the web page template, all of the artwork that appears in the theme is rasterized into 11 images, shown in FIG. **10** as **1**, **2a**, **2b**, **2c**, **3a**, **3b**, **3c**, **4a**, **4b**, **4c**, **5**. The images **3a**, **3b**, **3c** are patterns that repeat vertically (and so may be rendered at less than the whole height indicated.) After rasterizing the page into the aforementioned images, the web page template building tool then constructs an HTML table with the cells illustrated in FIG. **11** labeled Top, Left, Body, Right, and Bottom.

The “top” cell in FIG. **11** contains only image **1** (and so the cell is exactly the same size as the image.) The “left” cell in FIG. **11** contains image **3a** as a background image. It also contains a div with “position=relative”, and inside that div, image **2a** with “position=absolute”. The “middle” cell in FIG. **11** is similar; it contains image **3b** as a background image. It also contains a div with “position=relative”. Inside that div is image **2b** with “position=absolute”, and also all of the user-entered site content. The “right” cell in FIG. **11** is exactly analogous to the “left” cell (image **3c** and **2c**, accordingly). The “bottom” cell in FIG. **11** contains a div with “position=relative”. Inside that div, images **4a**, **4b**, and **4c** are positioned absolutely (with a negative ‘top’ coordinate) to put them at the bottom of the previous table cells. The div also contains image **5** with “position=absolute”. The middle row has a height specified, so that it is guaranteed to be sufficiently tall enough to contain images **2a**, **2b**, **2c** and images **4a**, **4b**, **4c**. Additionally, if images **3a**, **3b**, and **3c** are taller than one pixel, a JavaScript executes to increase the height of the middle row so that, once the text is added, it is a multiple of the pattern repeat—this allows patterns to be repeated across the entire website.

The navigation buttons are rendered in the “left” table cell, but uses absolute positioning for the buttons so they may appear in other cells as necessary. The navigational area can also include background imagery that grows or shrinks depending on the number of buttons on the site. Vertically-

oriented navigational areas can grow vertically. The upper guide may be automatically moved down the page so that the entire navigational area appears above the growable section of the page. This means the navigational area background will always be in images **1**, **2a**, **2b**, and **2c** only.

The images and controls that make up a theme are specified in absolute coordinates. For each of the images (**1**, **2a**, **2b**, . . . , **4c**, **5**) a bitmap of the appropriate size is created, and portions of the theme images are copied into them using GDI+. For example, if the “lower guide” is at vertical position **700**; the “body content rectangle” has its bottom at position **800** and it’s left-edge at position **200**, then for image **4a** an image 200 pixels wide by 100 pixels tall is created, and all of the theme imagery that occurs in the rectangle (0,700)-(200, 800) is flattened.

The result is a web page template that grows and shrinks according to the amount of content inserted in the auto-expanding user-editable content containers by an end user and that is reliably displayable in a multitude of different browsers and display types.

Preferably, the web page template building tool **82** retrieves at least one graphical element (for example a customer’s logo) from an electronic design editable by the document design tool and inserts the at least one graphical element into the website template. In an exemplary embodiment, the web page template building tool **82** pre-populates the web page template with content retrieved from an electronic design of a product designed to be printed which is open in the document design tool.

FIG. **12** is a flowchart of an exemplary embodiment of the operation of an auto-expanding user-editable content container when content is added by an end user. As illustrated, user selection of the auto-expanding user-editable content container is monitored (step **1201**), and the amount of text or other content added to the container is monitored (step **1202**). If it is detected that the size of the content exceeds the current sized of the container (step **1203**), then the container is expanded by vertically repeating the repeatable area (defined as the area between the horizontal guides **432**, **433**) (step **1204**). If it is detected that the size of the content is such that an instance of the repeatable area can be removed from the container and still fit the content therein (step **1205**), then one or more repeatable areas are removed from the container (step **1206**). The container and user content is rerendered on the user’s display (step **1207**). Thus, the content between the guides is repeated or removed to most efficiently match the amount of text (and/or other user-inserted content) in the auto-expanding user-editable content container. The implementation of the auto-expanding user-editable content container is preferably implemented using JavaScript.

FIG. **13** is a flowchart of an exemplary embodiment of the operation of an auto-expanding navigational area when navigation buttons are added or removed from a navigational area by an end user. As illustrated, user selection of the auto-expanding navigational area is monitored (step **1301**). User requests are monitored (step **1302**). If a user request to add a navigation button is detected (step **1303**), the navigational area is partitioned into three sections, including a top or left section, a repeatable middle section, and bottom or right section (step **1304**), as previously discussed with respect to FIGS. **7A** and **7B**. The repeatable middle section is repeated once (as illustrated in FIGS. **7A** and **7B**) to add the button (step **1305**). If a user request to remove a navigation button is detected (step **1306**), if there is only one button, the action is prevented. If there is at least two buttons, then an instance of the repeatable middle section is removed from the navigational area.

11

tional area and the remaining sections joined (step 1307). The navigational area is then re-rendered on the user's display (step 1308).

While exemplary embodiments of the invention have been discussed, the described embodiment is to be considered as illustrative rather than restrictive. The scope of the invention is as indicated in the following claims and all equivalent methods and systems.

What is claimed is:

1. A web page template building system for generating a flexible web page template that may be customized by a user, comprising:

a user interface comprising editing controls and a workspace for designing a web page template, the web page template comprising at least one auto-expanding user-editable content container which automatically expands and shrinks to fit content inserted by a user therein,

the editing controls comprising at least a user-adjustable upper horizontal guide and a user-adjustable lower horizontal guide displayed and associated with the at least one auto-expanding user-editable content container in the work area of the user interface, the upper and lower user-adjustable guides being vertically user-adjustable to define a single instance of a middle region of the content container, the single instance of the middle region comprising the area between the upper and lower user-adjustable guides,

wherein the at least one auto-expanding user-editable content container has associated thereto a control configured to monitor the size of user-inserted content therein relative to the size of the container, and if the content size exceeds the container size, repeats an instance of the middle portion of the container to expand the size of the container, and if the content size is such that an instance of the middle portion of the container can be removed and still fit within the container, removes an instance of the middle portion of the container to shrink the size of the container.

2. The web page template building system of claim 1, wherein the editing controls allow a template designer designing the template to insert artwork in the at least one

12

auto-expanding user-editable content container, wherein the artwork is configured to be rendered as background to content inserted by a user using the web page template.

3. The web page template building system of claim 2, wherein at least one of the editing controls operates to flatten the template-designer-inserted artwork within the at least one auto-expanding user-editable content container into a background layer of the at least one auto-expanding user-editable content container such that user-inserted content in the at least one auto-expanding user-editable content container as inserted by a user of the template in designing a web page is rendered in a layer over the flattened artwork in the background layer.

4. The web page template building system of claim 2, wherein the template-designer-inserted artwork positioned between the upper and lower horizontal guides is characterized only by either no variation in the vertical direction or a repeating pattern having a repeating frequency.

5. The web page template building system of claim 1, the web page template further comprising an auto-expanding navigational area which is configured to automatically expand and contract as navigation buttons are added and removed by an end user of the template,

wherein the auto-expanding navigational area is configured within the work area of the user interface and comprises a first section including a first edge of a with a first outer, the upper and lower adjustable horizontal guide and the lower horizontal guide being vertically adjustable to define a middle region of the content container, wherein the at least one auto-expanding user-editable content container has associated thereto a control configured to monitor the size of user-inserted content therein relative to the size of the container, and if the content size exceeds the container size, repeats an instance of the middle portion of the container to expand the size of the container, and if the content size is such that an instance of the middle portion of the container can be removed and still fit within the container, removes an instance of the middle portion of the container to shrink the size of the container.
